Grouping and summarizing

The GRAPH Courses team

November 2022

This document serves as an accompaniment for a lesson found on https://thegraphcourses.org.

The GRAPH Courses is a project of the Global Research and Analyses for Public Health (GRAPH) Network, with the support of the World Health Organization (WHO) and other partners

Introduction
Learning objectives
The Yaounde COVID-19 dataset
What are summary statistics?
<pre>Introducing dplyr::summarize()</pre>
Grouped summaries with dplyr::group by()
Grouping by multiple variables (nested grouping)
Ungrouping with dplyr::ungroup() (why and how)
Counting rows
Counting rows that meet a condition
dplyr::count()
Including missing combinations in summaries
Wrap-up

Introduction

You currently know how to keep your data entries of interest, how keep relevant variables and how to modify them or create new ones.

Now, we will take your data wrangling skills one step further by understanding how to easily extract summary statistics, through the verb summarize(), such as calculating the mean of a variable.

Moreover, we will begin exploring a crucial verb, $group_by()$, capable of grouping your variables together to perform grouped operations on your data set.

Let's go!

Learning objectives

- 1. You can use dplyr::summarize() to extract summary statistics from datasets.
- 2. You can use <code>dplyr::group_by()</code> to group data by one or more variables before performing operations on them.
- 3. You understand why and how to ungroup grouped data frames.
- 4. You can use dplyr::n() together with group_by()-summarize() to count rows per group.
- 5. You can use sum() together with group_by()-summarize() to count rows that meet a condition.
- 6. You can use dplyr::count() as a handy function to count rows per group.

The Yaounde COVID-19 dataset

In this lesson, we will again use data from the COVID-19 serological survey conducted in Yaounde. Cameroon.

```
yaounde <- read_csv(here::here('data/yaounde_data.csv'))

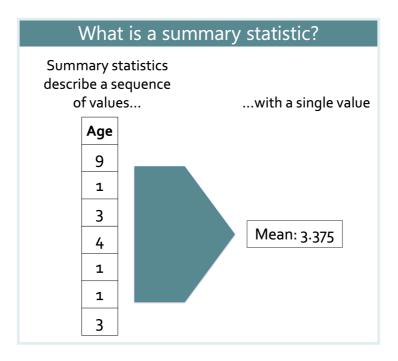

# A smaller subset of variables
yao <- yaounde %>% select(
   age, age_category_3, sex, weight_kg, height_cm,
   neighborhood, is_smoker, is_pregnant, occupation,
   treatment_combinations, symptoms, n_days_miss_work, n_bedridden_days,
   highest_education, igg_result)
```

```
## # A tibble: 971 × 15
##
    age age_category_3 sex weight_kg height_cm
## <dbl> <chr> <chr> <dbl> <dbl>
## 1 45 Adult
                     Female
                                95
## 2
      55 Adult
                     Male
                                 96
                                         185
## 3
      23 Adult
                                  74
                     Male
                                          180
                     Female
## 4 20 Adult
                                 70
                                          164
                                 67
## 5 55 Adult
                     Female
                                          147
## 6 17 Child
                     Female
                                 65
                                          162
## 7
      13 Child
                     Female
                                 65
                                          150
## 8 28 Adult
## 9 30 Adult
                     Male
                                  62
                                          173
                     Male
                                  7.3
                                          170
## 10
      13 Child
                      Female
                                  56
                                          153
## # ... with 961 more rows, and 10 more variables:
## # neighborhood <chr>, is smoker <chr>, ...
```

See the first lesson in this chapter for more information about this dataset.

What are summary statistics?

A summary statistic is a single value (such as a mean or median) that describes a sequence of values (typically a column in your dataset).

Summary statistics can describe the center, spread or range of a variable, or the counts and positions of values within that variable. Some common summary statistics are shown in the diagram below:

Examples of summary statistics

Summary statistic	R code	Output
Counts		
No. of elements	<pre>dplyr::n(age)</pre>	6
No. of distinct elements	<pre>dplyr::n_distinct(age)</pre>	4
Position		
First element	<pre>dplyr::first(age)</pre>	9
Last element	<pre>dplyr::last(age)</pre>	2
3rd element	<pre>dplyr::nth(age, 3)</pre>	4
Center		
Mean	mean(age)	3.3
Median	median(age)	2
Spread		
Standard deviation	sd(age)	2.9
Interquartile range	IQR(age)	1.5
Range		
Minimum	min(age)	1
Maximum	<pre>max(age)</pre>	9
25th quantile	quantile(age, 0.25)	2

Computing summary statistics is a very common operation in most data analysis workflows, so it will be important to become fluent in extracting them from your datasets. And for this task, there is no better tool than the {dplyr} function summarize()! So let's see how to use this powerful function.

Introducing dplyr::summarize()

To get started, it is best to first consider how to get simple summary statistics *without* using summarize(), then we will consider why you *should* actually use summarize().

Imagine you were asked to find the mean age of respondents in the yao data frame. How might you do this in base R?

First, recall that the dollar sign function, \$, allows you to extract a data frame column to a vector:

```
yao$age # extract the `age` column from `yao`
```

To obtain the mean, you simply pass this yao\$age vector into the mean () function:

```
mean(yao$age)
```

```
## [1] 29.01751
```

And that's it! You now have a simple summary statistic. Extremely easy, right?

So why do we need <code>summarize()</code> to get summary statistics if the process is already so simple without it?We'll come back to the <code>why</code> question soon. First let's see <code>how</code> to obtain summary statistics with <code>summarize()</code>.

Going back to the previous example, the correct syntax to get the mean age with summarize() would be:

```
yao %>%
   summarize(mean_age = mean(age))

## # A tibble: 1 × 1
## mean_age
## <dbl>
## 1 29.0
```

The anatomy of this syntax is shown below. You simply need to input name of the new column (e.g. mean_age), the summary function (e.g. mean()), and the column to summarize (e.g. age).

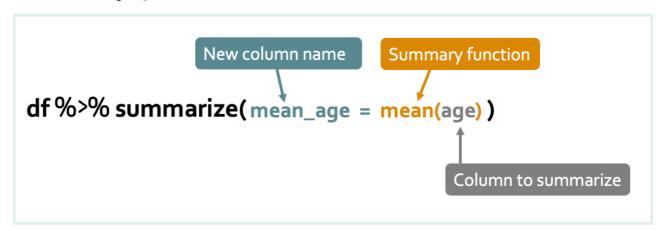

Fig. Basic syntax for the summarize () function.

You can also compute multiple summary statistics in a single summarize () statement. For example, if you wanted both the mean and the median age, you could run:

```
## # A tibble: 1 × 2
## mean_age median_age
## <dbl> <dbl>
## 1 29.0 26
```

Nicel

Now, you should be wondering why summarize() puts the summary statistics into a data frame, with each statistic in a different column.

The main benefit of this data frame structure is to make it easy to produce *grouped* summaries (and creating such grouped summaries will be the primary benefit of using summarize()).

We will look at these grouped summaries in the next section. For now, attempt the practice questions below.

Use summarize() and the relevant summary functions to obtain the mean, median and standard deviation of respondent weights from the weight kg variable of the yao data frame.

Your output should be a data frame with three columns named as shown below:

mean_weight_kg median_weight_kg sd_weight_kg

Use summarize() and the relevant summary functions to obtain the minimum and maximum respondent heights from the $height_cm$ variable of the yao data frame.

Your output should be a data frame with two columns named as shown below:

min_height_cm max_height_cm

```
Q_height_summary <-
   yao %>%
```

```
PRACTICE

(in RMD)
```

```
.CHECK_Q_height_summary()
.HINT_Q_height_summary()
```

Grouped summaries with dplyr::group by()

As its name suggests, dplyr::group_by() lets you group a data frame by the values in a variable (e.g. male vs female sex). You can then perform operations that are split according to these groups.

What effect does <code>group_by()</code> have on a data frame? Let's try to group the <code>yao</code> data frame by sex and observe the effect:

```
yao %>%
group_by(sex)
```

```
## # A tibble: 971 × 15
## # Groups: sex [2]
      age age category 3 sex weight kg height cm
##
    ##
## 1
      45 Adult
                    Female
                               95
                                      169
## 2
      55 Adult
                   Male
                               96
                                       185
                   Male
  3
      23 Adult
                               74
##
                                       180
     20 Adult
                   Female
##
  4
                               70
                                       164
## 5
     55 Adult
                   Female
                              67
                                       147
## 6
     17 Child
                   Female
                               65
## 7 13 Child
                   Female
                               65
                                       150
## 8 28 Adult
                   Male
                               62
                                       173
## 9
     30 Adult
                   Male
                               7.3
                                       170
     13 Child
## 10
                    Female
                              56
                                      153
## # ... with 961 more rows, and 10 more variables:
     neighborhood <chr>, is smoker <chr>, ...
```

Hmm. Apparently nothing happened. The one thing you *might* notice is a new section in the header that tells you the grouped-by variable—sex—and the number of groups—2:

```
# A tibble: 971 × 10
# Groups: sex [2]
```

Apart from this header however, the data frame appears unchanged.

But watch what happens when we chain the group_by() with the summarize() call we used in the previous section:

```
yao %>%
  group_by(sex) %>%
  summarize(mean_age = mean(age))
```

You get a different summary statistic for each group! The statistics for women are in one row and those for men are in another. (From this output data frame, you can tell that, for example, the mean age for female respondents is 29.5, while that for male respondents is 28.4)

As was mentioned earlier, this kind of grouped summary is the primary reason the summarize() function is so useful!

Let's see another example of a simple group by () + summarize () operation.

Suppose you were asked to obtain the maximum and minimum weights for individuals in different neighborhoods in the yao data frame. First you would group_by() the neighbourhood variable, then call the max() and min() functions inside summarize():

```
## # A tibble: 9 \times 3
  neighborhood max weight min weight
## <chr> <dbl> <dbl>
                    128
## 1 Briqueterie
                              20
## 2 Carriere
                    129
                               14
## 3 Cité Verte
                    118
                               16
                     135
## 4 Ekoudou
                                15
                     96
                               19
## 5 Messa
## 6 Mokolo
                    162
                               16
## 7 Nkomkana
                    161
                               15
                    105
                               15
## 8 Tsinga
## 9 Tsinga Oliga
                    100
                                17
```

Great! With just a few code lines you are able to extract guite a lot of information.

Let's see one more example for good measure. The variable $n_{days_miss_work}$ tells us the number of days that respondents missed work due to COVID-like symptoms. Individuals who reported no COVID-like symptoms have an NA for this variable:

```
yao %>%
select(n_days_miss_work)
```

```
## # A tibble: 971 × 1
## n days miss work
##
              <dbl>
## 1
                  0
## 2
                  NA
## 3
                  NA
##
   4
                   7
## 5
                  NA
## 6
                  7
## 7
                  0
## 8
                  0
## 9
                  0
## 10
## # ... with 961 more rows
```

To count the total number of work days missed for each sex group, you could try to run the sum() function on the n days miss work variable:

```
yao %>%
group_by(sex) %>%
summarise(total_days_missed = sum(n_days_miss_work))
```

Hmmm. This gives you NA results because some rows in the $n_{days_miss_work}$ column have NAs in them, and R cannot find the sum of values containing an NA. To solve this, the argument na.rm = TRUE is needed:

```
yao %>%
  group_by(sex) %>%
  summarise(total_days_missed = sum(n_days_miss_work, na.rm = TRUE))
```

The output tells us that across all women in the sample, 256 work days were missed due to COVID-like symptoms, and across all men, 272 days.

So hopefully now you see why summarize() is so powerful. In combination with group_by(), it lets you obtain highly informative grouped summaries of your datasets with very few lines of code.

Producing such summaries is a very important part of most data analysis workflows, so this skill is likely to come in handy soon!

summarize() produces "Pivot Tables"

Use group_by() and summarize() to obtain the mean weight (kg) by smoking status in the yao data frame. Name the average weight column weight_mean

The output data frame should look like this:

is_smoker	weight_mean
Ex-smoker	
Non-smoker	
Smoker	
NA	

Use <code>group_by()</code>, <code>summarize()</code>, and the relevant summary functions to obtain the minimum and maximum heights for each sex in the <code>yao</code> data frame.

Your output should be a data frame with three columns named as shown below:

sex	min_height_cm	max_height_cm
Female		
Male		

Use $group_by()$, summarize(), and the sum() function to calculate the total number of bedridden days (from the $n_bedridden_days$ variable) reported by respondents of each sex.

Your output should be a data frame with two columns named as shown below:

```
sex total_bedridden_days
Female
Male
```

Grouping by multiple variables (nested grouping)

It is possible to group a data frame by more than one variable. This is sometimes called "nested" grouping.

Let's see an example. Suppose you want to know the mean age of men and women *in each neighbourhood* (rather than the mean age of *all* women), you could put both sex and neighborhood in the group by () statement:

```
yao %>%
  group_by(sex, neighborhood) %>%
  summarize(mean_age = mean(age))

## `summarise()` has grouped output by 'sex'. You can override using the
`.groups`
## argument.

## # A tibble: 18 × 3
## # Groups: sex [2]
```

```
<chr> <chr>
##
                        <dbl>
## 1 Female Briqueterie
                          31.6
                         28.2
## 2 Female Carriere
## 3 Female Cité Verte
                         31.8
## 4 Female Ekoudou
                         29.3
## 5 Female Messa
                         30.2
   6 Female Mokolo
##
                         28.0
                         33.0
##
  7 Female Nkomkana
## 8 Female Tsinga
## 9 Female Tsinga Oliga
                         24.3
## 10 Male Briqueterie
                         33.7
## 11 Male Carriere
                          30.0
## 12 Male Cité Verte
                         27.0
## 13 Male Ekoudou
                         25.2
## 14 Male Messa
                         23.9
## 15 Male Mokolo
                         30.5
                         29.8
## 16 Male Nkomkana
                         28.8
## 17 Male Tsinga
## 18 Male Tsinga Oliga
                         24.3
```

From this output data frame you can tell that, for example, women from Briqueterie have a mean age of 31.6 years, while men from Briqueterie have a mean age of 33.7 years.

The order of the columns listed in <code>group_by()</code> is interchangeable. So if you run <code>group_by(neighborhood, sex)</code> instead of <code>group_by(sex, neighborhood)</code>, you'll get the same result, although it will be ordered differently:

```
vao %>%
 group by (neighborhood, sex) %>%
 summarize(mean age = mean(age))
 ## `summarise()` has grouped output by 'neighborhood'. You can override using
 the
 ## `.groups` argument.
 ## # A tibble: 18 × 3
 ## # Groups: neighborhood [9]
     neighborhood sex mean age
            <chr>
 ##
     <chr>
                       <dhl>
 ## 1 Briqueterie Female
                          31.6
 ## 2 Briqueterie Male
                          33.7
                          28.2

## 16 Tsinga
               Male
                          28.8
## 17 Tsinga Oliga Female
                         24.3
## 18 Tsinga Oliga Male
                         24.3
```

Now the column order is different: neighborhood is the first column, and sex is the second. And the row order is also different: rows are first ordered by neighborhood, then ordered by sex within each neighborhood.

But the actual summary statistics are the same. For example, you can again see that women from Briqueterie have a mean age of 31.6 years, while men from Briqueterie have a mean age of 33.7 years.

Using the yao data frame, group your data by gender (sex) and treatments (treatment_combinations) using group_by. Then, using summarize() and the relevant summary function, calculate the mean weight (weight kg) for each group.

Your output should be a data frame with three columns named as shown below:

sex treatment_combinations mean_weight_kg

Using the yao data frame, group your data by age category (age_category_3), gender (sex), and IgG results (igg_result) using group_by. Then, using summarize() and the relevant summary function, calculate the mean number of bedridden days (n_bedridden_days) for each group.

Your output should be a data frame with four columns named as shown below:

age_category_3 sex igg_result mean_n_bedridden_days

Ungrouping with dplyr::ungroup() (why and how)

When you <code>group_by()</code> more than one variable before using <code>summarize()</code>, the output data frame is still grouped. This persistent grouping can have unwanted downstream effects, so you will sometimes need to use <code>dplyr::ungroup()</code> to ungroup the data before doing further analysis.

To understand *why* you should ungroup () data, first consider the following example, where we group by only one variable before summarizing:

The data comes out like a normal data frame; it is not grouped. You can tell this because there is no information about groups in the header.

But now consider when you group by two variables before summarizing:

```
vao %>%
 group by (sex, neighborhood) %>%
 summarize(mean age = mean(age))
 ## `summarise()` has grouped output by 'sex'. You can override using the
 `.groups`
 ## argument.
 ## # A tibble: 18 × 3
 ## # Groups: sex [2]
 ## sex neighborhood mean age
     <chr> <chr> <chr> <dbl>
 ## 1 Female Briqueterie
                          31.6
 ## 2 Female Carriere
                            28.2
                           31.8
 ## 3 Female Cité Verte
                           29.3
 ## 4 Female Ekoudou
 ## 5 Female Messa
                           30.2
                           28.0
 ## 6 Female Mokolo
   6 Female Nomkana
                            33.0
 ##
                            30.6
 ## 8 Female Tsinga
 ## 9 Female Tsinga Oliga
                           24.3
```

```
## 10 Male Briqueterie
                        33.7
## 11 Male Carriere
                         30.0
                        27.0
## 12 Male Cité Verte
## 13 Male Ekoudou
                        25.2
## 14 Male Messa
                        23.9
## 15 Male Mokolo
                        30.5
## 16 Male Nkomkana
                        29.8
                        28.8
## 17 Male Tsinga
## 18 Male Tsinga Oliga
                        24.3
```

Now the header tells you that the data is still grouped by the first variable in $group_by()$, sex:

```
# A tibble: 18 × 3

## Groups: sex [2]
```

What is the implication of this persistent grouping in the data frame? It means that the data frame may exhibit what seems like weird behavior when you try to apply some {dplyr} functions on it.

For example, if you try to select() a single variable, perhaps the mean_age variable, you should normally be able to just use select (mean_age):

```
yao %>%
  group_by(sex, neighborhood) %>%
  summarize(mean_age = mean(age)) %>%
  select(mean_age) # doesn't work as expected
```

```
## `summarise()` has grouped output by 'sex'. You can override using the
`.groups`
## argument.
## Adding missing grouping variables: `sex`
## # A tibble: 18 × 2
## # Groups: sex [2]
##
    sex mean age
     <chr> <dbl>
##
## 1 Female 31.6
## 2 Female
              28.2
## 3 Female
              31.8
              29.3
## 4 Female
## 5 Female
              30.2
              28.0
## 6 Female
## 7 Female
              33.0
## 8 Female
              30.6
## 9 Female
              24.3
              33.7
## 10 Male
## 11 Male
              30.0
## 12 Male
              27.0
```

```
## 13 Male 25.2

## 14 Male 23.9

## 15 Male 30.5

## 16 Male 29.8

## 17 Male 28.8

## 18 Male 24.3
```

But as you can see, the grouped-by variable, sex, is still selected, even though we only asked for $mean_age$ in the select() statement.

This is one of the many examples of unique behaviors of grouped data frames. Other dplyr verbs like filter(), mutate() and arrange() also act in special ways on grouped data. We will address this in detail in a future lesson.

So you now know *why* you should ungroup data when you no longer need it grouped. Let's now see *how* to ungroup data. It's quite simple: just add the ungroup () function to your pipe chain. For example:

```
yao %>%
  group_by(sex, neighborhood) %>%
  summarize(mean_age = mean(age)) %>%
  ungroup()
```

```
## `summarise()` has grouped output by 'sex'. You can override using the
`.groups`
## argument.
```

```
## # A tibble: 18 × 3
## sex neighborhood mean age
    <chr> <chr> <dbl>
##
## 1 Female Briqueterie
                         31.6
                         28.2
   2 Female Carriere
                         31.8
## 3 Female Cité Verte
## 4 Female Ekoudou
                         29.3
## 5 Female Messa
                         30.2
                         28.0
## 6 Female Mokolo
   7 Female Nkomkana
                         33.0
##
                         30.6
## 8 Female Tsinga
## 9 Female Tsinga Oliga
                         24.3
## 10 Male Briqueterie
                         33.7
## 11 Male Carriere
                         30.0
## 12 Male Cité Verte
                         27.0
                         25.2
## 13 Male Ekoudou
## 14 Male Messa
                         23.9
## 15 Male Mokolo
## 15 Male Monort Workship Male Nkomkana
                         30.5
                         29.8
## 17 Male Tsinga
                          28.8
## 18 Male Tsinga Oliga
                         24.3
```

Now that the data frame is ungrouped, it will behave like a normal data frame again. For example, you can select() any column(s) you want; you won't have some unwanted columns tagging along:

```
yao %>%
 group by (sex, neighborhood) %>%
 summarize(mean age = mean(age)) %>%
 ungroup() %>%
 select(mean age)
 ## `summarise()` has grouped output by 'sex'. You can override using the
 `.groups`
 ## argument.
 ## # A tibble: 18 × 1
 ## mean age
       <dbl>
 ##
       31.6
 ## 1
 ## 2
        28.2
 ## 3
        31.8
 ## 4
        29.3
 ## 5
         30.2
 ## 6
        28.0
 ##
   7
        33.0
        30.6
 ## 8
 ## 9
        24.3
 ## 10
        33.7
       30.0
 ## 11
## 12
 ## 13
        25.2
## 14
        23.9
         30.5
 ## 15
 ## 16
        29.8
## 17 28.8
## 18 24.3
```

Counting rows

You can do a lot of data science by just *counting* and occasionally *dividing*. - Hadley Wickham, Chief Scientist at RStudio

A common data summarization task is counting how many observations (rows) there are for each group. You can achieve this with the special n() function from {dplyr}, which is specifically designed to be used within summarise().

For example, if you want to count how many individuals are in each neighborhood group, you would run:

```
yao %>%
  group_by(neighborhood) %>%
  summarize(count = n())
```

As you can see, the n () function does not require any arguments. It just "knows its job" in the data frame!

Of course, you can include other summary statistics in the same summarize() call. For example, below we also calculate the mean age per neighborhood.

Group your yao data frame by the respondents' occupation (occupation) and use summarize() to create columns that show:

- how many individuals there are with each occupation (think of the n () function)
- the mean number of work days missed (n_days_miss_work) by those in that occupation

Your output should be a data frame with three columns named as shown below:

occupation count mean_n_days_miss_work

```
Q_occupation_summary <-
yao %>%
______
```

Counting rows that meet a condition

Rather than counting all rows as above, it is sometimes more useful to count just the rows that meet specific conditions. This can be done easily by placing the required conditions within the sum() function.

For example, to count the number of people under 18 in each neighborhood, you place the condition age < 18 inside sum():

```
yao %>%
  group_by(neighborhood) %>%
  summarize(count_under_18 = sum(age < 18))</pre>
```

```
## # A tibble: 9 × 2
   neighborhood count_under_18
## <chr>
                        <int>
## 1 Briqueterie
## 2 Carriere
                             58
## 3 Cité Verte
                             19
## 4 Ekoudou
                             66
                             18
## 5 Messa
## 6 Mokolo
                             32
## 7 Nkomkana
                            22
## 8 Tsinga
                             23
## 9 Tsinga Oliga
```

Similarly, to count the number of people with doctorate degrees in each neighborhood, you place the condition highest education == "Doctorate" inside sum():

```
yao %>%
  group_by(neighborhood) %>%
  summarize(count_with_doctorates = sum(highest_education == "Doctorate"))
```

Under the hood: counting with conditions

Why are you able to use sum() which is meant to add numbers, on a condition like highest education == "Doctorate"?

Using sum() on a condition works because the condition evaluates to the Boolean values TRUE and FALSE. And these Boolean values are treated as numbers (where TRUE equals 1 and FALSE equals 0), and numbers can, of course, be summed.

The code below demonstrates what is going on under the hood in a stepby-step way. Run through it and see if you can follow.

CHALLENGE

```
demo_of_condition_sums <- yao %>%
  select(highest_education) %>%
  mutate(with_doctorate = highest_education == "Doctorate") %>%
  mutate(numeric_with_doctorate = as.numeric(with_doctorate))

demo_of_condition_sums
```

```
## # A tibble: 971 × 3
   highest_education with doctorate numeric with doctorate
##
     <chr>
                      <lq1>
                                                      <dbl>
## 1 Secondary
                      FALSE
## 2 University
                                                          0
                      FALSE
## 3 University
                                                          0
                      FALSE
##
   4 Secondary
                       FALSE
                                                          0
## 5 Primary
                      FALSE
## 6 Secondary
                      FALSE
                                                          0
## 7 Secondary
                                                          0
                      FALSE
## 8 Doctorate
                                                          1
                      TRUE
   9 Secondary
                       FALSE
```

```
## 10 Secondary FALSE 0
## # ... with 961 more rows

The numeric values can then be added to produce a count of rows fulfilling the condition highest_education == "Doctorate":

CHALLENGE

demo_of_condition_sums %>%
    summarize(count_with_doctorate = sum(numeric_with_doctorate))

## # A tibble: 1 × 1
## count_with_doctorate
## < <dbl>
## 1 1 17
```

For a final illustration of counting with conditions, consider the treatment_combinations variable, which lists the treatments received by people with COVID-like symptoms. People who received no treatments have an NA value:

```
yao %>%
select(treatment_combinations)
```

```
## # A tibble: 971 × 1
##
    treatment combinations
##
     <chr>
## 1 Paracetamol
## 2 <NA>
## 3 <NA>
## 4 Antibiotics
## 5 <NA>
## 6 Paracetamol--Antibiotics
   7 Traditional meds.
##
## 8 Paracetamol
## 9 Paracetamol--Traditional meds.
## 10 <NA>
## # ... with 961 more rows
```

If you want to count the number of people who received *no treatment*, you would sum up those who meet the is.na(treatment combinations) condition:

```
yao %>%
  group_by(neighborhood) %>%
  summarize(unknown_treatments = sum(is.na(treatment_combinations)))
```

```
## # A tibble: 9 × 2
## neighborhood unknown treatments
## <chr>
## 1 Briqueterie
                                82
## 2 Carriere
                               192
## 3 Cité Verte
                                46
## 4 Ekoudou
                                133
## 5 Messa
                                35
## 6 Mokolo
                                65
## 7 Nkomkana
                                53
## 8 Tsinga
                                56
## 9 Tsinga Oliga
                                 47
```

These are the people with NA values for the $treatment_combinations$ column.

To count the people who *did* receive some treatment, you can simply negate the is.na() function with !:

```
yao %>%
  group_by(neighborhood) %>%
  summarize(known_treatments = sum(!is.na(treatment_combinations)))
```

```
## # A tibble: 9 × 2
## neighborhood known_treatments
## <chr>
                           <int>
## 1 Briqueterie
                               44
## 2 Carriere
                              26
## 3 Cité Verte
## 4 Ekoudou
                              57
## 5 Messa
                              13
## 6 Mokolo
                              31
## 7 Nkomkana
                              22
                              25
## 8 Tsinga
## 9 Tsinga Oliga
                              20
```

Group your yao data frame by the respondents' symptoms (symptoms) and use the sum() function to count how many adults have each symptom combination.

Your output should be a data frame with two columns named as shown below:

symptoms sum_adults

```
PRACTICE
oro
```

dplyr::count()

The dplyr::count() function wraps a bunch of things into one beautiful friendly line of code to help you find counts of observations by group.

Let's use dplyr::count() on our occupation variable:

```
yao %>% count(occupation)
```

```
## # A tibble: 28 × 2
    occupation
##
##
     <chr>
                                          <int>
## 1 Farmer
## 2 Farmer--Other
                                             1
## 3 Home-maker
                                             65
## 4 Home-maker--Farmer
                                             2
##
   5 Home-maker--Informal worker
   6 Home-maker--Informal worker--Farmer
##
  7 Home-maker--Trader
                                             3
## 8 Informal worker
                                           189
## 9 Informal worker--Other
                                              2
## 10 Informal worker--Trader
## # ... with 18 more rows
```

Note that this is the same output as:

```
yao %>%
  group_by(occupation) %>%
  summarize(n = n())
```

```
## # A tibble: 28 × 2
    occupation
##
                                             n
     <chr>
##
                                          <int>
## 1 Farmer
                                              5
## 2 Farmer--Other
                                             1
   3 Home-maker
                                             65
##
##
   4 Home-maker--Farmer
   5 Home-maker--Informal worker
##
## 6 Home-maker--Informal worker--Farmer
   7 Home-maker--Trader
                                             3
##
## 8 Informal worker
                                            189
   9 Informal worker--Other
```

```
## 10 Informal worker--Trader
## # ... with 18 more rows
```

You can also apply dplyr::count() in a nested fashion:

```
yao %>% count(sex, occupation)
```

```
## # A tibble: 40 × 3
##
     sex occupation
     <chr> <chr>
##
                                                <int>
## 1 Female Farmer
## 2 Female Home-maker
                                                   65
## 3 Female Home-maker--Farmer
                                                    2
## 4 Female Home-maker--Informal worker

## 10 Female Other
## # ... with 30 more rows
```

The <code>count()</code> verb gives you key information about your dataset in a very quick manner. Let's look at our IgG results stratified by age category and sex in one line of code.

Using the yao data frame, count the different combinations of gender (sex), age categories (age category 3) and IgG results (igg result).

Your output should be a data frame with four columns named as shown below:

sex age_category_3 igg_result n

```
Q_count_iggresults_stratified_by_sex_agecategories <-
  yao %>%
```

Using the yao data frame, count the different combinations of age categories (age_category_3) and number of bedridden days (n bedridden days).

Your output should be a data frame with three columns named as shown below:

The downside of count() is that it can only give you a single summary statistic in the data frame. When you use summarize() and n() you can include multiple summary statistics. For example:

```
yao %>%
 group by (sex, neighborhood) %>%
 summarize(count = n(),
           median age = median(age))
 ## `summarise()` has grouped output by 'sex'. You can override using the
 `.groups`
 ## argument.
 ## # A tibble: 18 × 4
 ## # Groups: sex [2]
 ##
     sex neighborhood count median age
      <chr> <chr> <int>
 ##
                              <dbl>
                                   28
 ## 1 Female Briqueterie
                          61
                         140
    2 Female Carriere
                                    25.5
   3 Female Cité Verte
 ##
                          44
                                   28
 ## 4 Female Ekoudou
                         110
                                   26.5
 ## 5 Female Messa
                           26
                                   27.5
                           53
 ## 6 Female Mokolo
                                   23
 ##
    7 Female Nkomkana
                           43
                                   28
                                   29
 ## 8 Female Tsinga
                           42
 ## 9 Female Tsinga Oliga
                          30
                                   23.5
 ## 10 Male Briqueterie
                           45
                                   28
           Carriere
                                   27
 ## 11 Male
                           96
 ## 12 Male
           Cité Verte
                           28
                                   22.5
 ## 13 Male Ekoudou
                           80
                                   21.5
                           22
                                   24.5
 ## 14 Male Messa
 ## 15 Male Mokolo
                           43
                                   32
 ## 16 Male Nkomkana
                           32
                                   27
 ## 17 Male Tsinga
                           39
                                   27
```

But count () can only yield counts:

18 Male Tsinga Oliga 37

```
yao %>%
  group_by(sex, neighborhood) %>%
  count()
```

21

```
## # A tibble: 18 × 3
## # Groups: sex, neighborhood [18]
## sex neighborhood n

                       32
## 17 Male Tsinga
                       39
## 18 Male Tsinga Oliga 37
```

Including missing combinations in summaries

When you use <code>group_by()</code> and <code>summarize()</code> on multiple variables, you obtain a summary statistic for every unique combination of the grouped variables. For instance, consider the code and output below, which counts the number of individuals in each age-sex group:

```
yao %>%
 group_by(sex, age_category_3) %>%
  summarise(number of individuals = n())
 ## `summarise()` has grouped output by 'sex'. You can override using the
 `.groups`
 ## argument.
 ## # A tibble: 6 \times 3
 ## # Groups: sex [2]
     sex age category 3 number of individuals
 ##
 ##
    <chr> <chr>
                                            <int>
 ## 1 Female Adult
                                              368
 ## 2 Female Child
                                              155
 ## 3 Female Senior
                                               26
 ## 4 Male Adult
                                               267
```

```
## 5 Male Child 136
## 6 Male Senior 19
```

In the output data frame, there is one row for each combination of sex and age group (Female–Adult, Female–Child and so on).

But what happens if one of these combinations is not present in the data?

Let's create an artificial example to observe this. With the code below, we artificially drop all male children from the yao data frame:

```
yao_no_male_children <-
yao %>%
filter(!(sex == "Male" & age_category_3 == "Child"))
```

Now if you run the same <code>group_by()</code> and <code>summarize()</code> call on <code>yao_no_male_children</code>, you'll notice the missing combination:

```
yao_no_male_children %>%
  group_by(sex, age_category_3) %>%
  summarise(number_of_individuals = n())
```

```
## `summarise()` has grouped output by 'sex'. You can override using the
`.groups`
## argument.
## # A tibble: 5 × 3
## # Groups: sex [2]
   sex age category 3 number of individuals
## <chr> <chr>
## 1 Female Adult
                                            368
## 2 Female Child
                                            155
## 3 Female Senior
                                             26
## 4 Male Adult
                                            267
## 5 Male Senior
                                            19
```

Indeed, there is no row for male children.

But sometimes it is useful to include such missing combinations in the output data frame, with an $\mathbb{N}\mathbb{A}$ or 0 value for the summary statistic.

To do this, you can run the following code instead:

```
yao no male children %>%
 # convert variables to factors
 mutate(sex = as.factor(sex),
       age category 3 = as.factor(age category 3)) %>%
  # Note the the .drop = FALSE argument
 group by (sex, age category 3, .drop = FALSE) %>%
 summarise(number of individuals = n())
 ## `summarise()` has grouped output by 'sex'. You can override using the
 `.groups`
 ## argument.
 ## # A tibble: 6 × 3
 ## # Groups: sex [2]
    sex age category 3 number of individuals
 ##
    <fct> <fct>
 ## 1 Female Adult
                                              368
 ## 2 Female Child
                                             155
 ## 3 Female Senior
                                              26
 ## 4 Male Adult
                                              267
```

What does the code do?

5 Male Child

6 Male Senior

• First it converts the grouping variables to factors with as.factor() (inside a mutate() call)

0

19

• Then it uses the argument .drop = FALSE in the group_by() function to avoid dropping the missing combinations.

Now you have a clear 0 count for the number of male children!

Let's see one more example, this time without artificially modifying our data.

The code below calculates the average age by sex and education group:

```
yao %>%
  group_by(sex, highest_education) %>%
  summarise(mean_age = mean(age))
```

```
## `summarise()` has grouped output by 'sex'. You can override using the
`.groups`
## argument.
```

```
## # A tibble: 13 \times 3
## # Groups: sex [2]
## sex highest education mean age
##
    <chr> <chr>
                              <dbl>
## 1 Female Doctorate
                                28
## 2 Female No formal instruction 45.6
## 3 Female No response
                                26.8
## 4 Female Primary
## 5 Female Secondary
                                28.8
## 6 Female University
                                 31.5
  7 Male Doctorate
##
                                 42.2
## 8 Male No formal instruction 37.9
## 9 Male No response
                                22
## 10 Male Other
                                 5.5
## 11 Male Primary
                                 22.9
## 12 Male Secondary
                                 29.4
## 13 Male University
                                 31.9
```

Notice that in the output data frame, there are 7 rows for men but only 6 rows for women, because no woman answered "Other" to the question on highest education level.

If you nonetheless want to include the "Female–Other" row in the output data frame, you would run:

```
yao %>%
 mutate(sex = as.factor(sex),
       highest education = as.factor(highest education)) %>%
 group by (sex, highest education, .drop = FALSE) %>%
 summarise(mean_age = mean(age))
 ## `summarise()` has grouped output by 'sex'. You can override using the
 .groups`
 ## argument.
 ## # A tibble: 14 × 3
 ## # Groups: sex [2]
 ##
     sex highest education mean_age
                                <dbl>
 ##
      <fct> <fct>
 ## 1 Female Doctorate
                                    28
 ## 2 Female No formal instruction
                                   45.6
 ## 3 Female No response
                                    35
 ## 4 Female Other
                                  NaN
 ##
   5 Female Primary
                                    26.8
 ## 6 Female Secondary
                                    28.8
 ## 7 Female University
                                    31.5
 ## 8 Male Doctorate
                                    42.2
 ## 9 Male No formal instruction 37.9
 ## 10 Male No response
                                    22
 ## 11 Male Other
                                    5.5
 ## 12 Male Primary
                                   22.9
```

13 Male Secondary 29.4 ## 14 Male University 31.9

> Using the yao data frame, let's calculate the median age when grouping by neighborhood, age_category, and gender

Note, we want all possible combinations of these three variables (not just those present in our data).

Pay attention to two data wrangling imperatives!

- convert your grouping variables to factors beforehand using mutate()
- calculate your statistic, the median, while removing any NA values.

Your output should be a data frame with four columns named as shown below:

neighborhood age_category_3 sex median_age

```
Q median age by neighborhood agecategory sex <-
  yao %>%
```

Why include missing combinations?

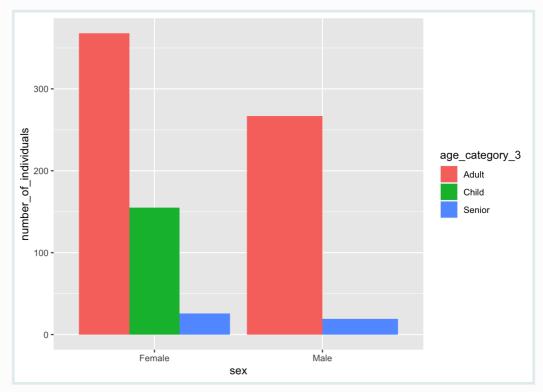

SIDE NOTE Above, we mentioned that including missing combinations is often useful in the data analysis workflow. Let's see one use case: plotting with {ggplot}. If you have not yet learned {ggplot}, that is okay, just focus on the plot outputs.

> To make a dodged bar chart with the age-sex counts of yao no male children, you could run:

```
## `summarise()` has grouped output by 'sex'. You can override
using the `.groups`
## argument.
```

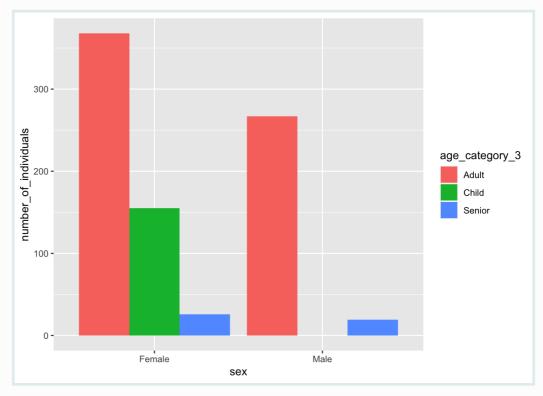

Not very elegant! Ideally there should be an empty space indicating 0 for the number of male children.

If you instead implement the procedure to include missing combinations, you get a more natural dodged bar plot, with an empty space for male children:

`summarise()` has grouped output by 'sex'. You can override
using the `.groups`
argument.

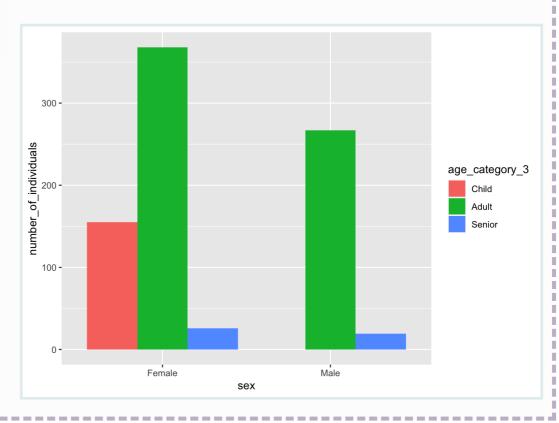

Much better!

By the way, this output can be improved slightly by setting the factor levels for age to their proper ascending order: first "Child", then "Adult" then "Senior":

`summarise()` has grouped output by 'sex'. You can override
using the `.groups`
argument.

SIDE NOTE

Wrap-up

You have now seen how to obtain quick summary statistics from your data, either for exploratory data or for further data presentation or plotting.

Additionally, you have discovered one of the marvels of $\{dplyr\}$, the possibility to group your data using group by ().

group_by() combined with summarize() is a one of the most common grouping manipulations.

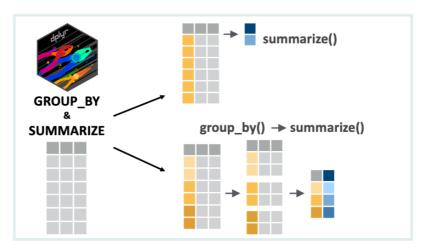

Fig: summarize() and group_by()

However, you can also combine $group_by()$ with many of the other {dplyr} verbs: this is what we will cover in our next lesson. See you soon!
